ABSTRACT

Chronic viral Hepatitis B virus (HBV) and Hepatitis C virus (HCV) remain a significant global public health problem and a major cause of liver-related morbidity and mortality in Central Africa with high endemicity among pregnant women. Both Hepatitis B and C can cause acute and chronic infections and are leading cases of liver cirrhosis and hepatocellular carcinoma. During pregnancy, screening for hepatitis B and C is crucial because both viruses can be transmitted from mother to child, with HBV being more prevalent than HCV, and both infections posing risks for mother-to-child transmission. HBV transmission is largely preventable with post-birth immunoprophylaxis (vaccine + HIBG), while HCV transmission is less efficient but potentially treated with antivirals to prevent vertical spread. This cross-sectional study at Bertoua Regional Hospital Cameroon (June 2025-January 2026) aimed at determining the Seroprevalence of viral Hepatitis B and C among 400 pregnant women attending the maternity unit; the majority of them (62%) were aged within (19-28). The overall seroprevalence was (7.25%): HBV (4%), HCV (2.25%), Co-infection HBV and HCV (1%). However, data determining the seroprevalence rate across both community and healthcare settings remain limited, hence the need of this research. The findings align with the World Health Organization as well as other organisms fighting for the elimination of viral Hepatitis such as the Centre of Disease Control and Prevention.

1. INTRODUCTION

Blood-borne pathogens, Hepatitis B virus (HBV) and Hepatitis C virus (HCV) remain significant global public health challenges contributing substantially to the burden of infectious diseases worldwide. Globally, over 254 million and 50 million people are estimated to be chronically infected with HBV and HCV, respectively. According to the WHO 2024, Global Hepatitis report (*WHO 2024*). Viral Hepatitis causes approximately 1.3 million deaths annually, ranking as the second leading infectious cause of death, comparable to tuberculosis.

Hepatitis B and C viruses are hepatotropic viruses responsible for the majority of viral hepatitis-related morbidity and mortality. Chronic infection can lead to liver cirrhosis, hepatocellular carcinoma (HCC), liver failure, and premature death: both viruses share similar transmission routes of contaminated sharps, sexual contact, household exposures, and unsafe medical practices. Despite the availability of effective HBV vaccine, HCV remains non-vaccine preventable, and a substantial proportion of infected individuals remain undiagnosed and untreated worldwide. Hepatitis B virus causes a common Public health problem in Cameroon and across Sub-Saharan Africa (*Abongwa L.E. et al 2015*). In Uganda, antenatal education was recommended because most pregnant women showed excessively low knowledge and misconceptions about HBV (*Nyanka-Mutyoba et al 2018*). Studies have reported a significant relationship between knowledge on the transmission/prevention of HBV and the spread of the infection (*Nyanka-Mutyoba et al 2018*).

Cameroon bears a significant burden based on the recent data, the Far North Region (specifically areas like Tokombéré and Mokolo) is a primary hotspot for high endemicity of HBV

among pregnant women in Cameroon with prevalence rates exceeding 10% while HCV shows a prevalence rate of 1.8% to 7.3%, where endemic transmission persists. This was a cross-sectional study whose aim was to determine the Seroprevalence rate and of viral Hepatitis B and C among pregnant women at the Bertoua Regional Hospital.

2. RELATED WORKS

A cross-sectional study (Ngwanou et al 2021;) was conducted in Congo with 457 pregnant women who attended antenatal care. Sociodemographic, obstetric, and previous medico-surgical data, as well as information related to women's HBV knowledge, were collected using a questionnaire. Most pregnant women were aged 20–24 years. Only 6.8% of respondents had knowledge of HBV, and the main source of this knowledge was health facilities (4.6%). Only 0.7% reported having been tested, whereas 98.5% said that they had not been offered a test. Overall, 18 (3.9%), participants were HBV positive and 22 (4.8%) were positive for HCV.

In 2017, a meta-analysis of (*Bigna JJ, Amougou et al 2017*) studied the seroprevalence of HCV in infections in Cameroon, the results showed that the prevalence was higher in the East region, in rural settings, and when using an enzyme immuno-assay technique for detecting antibodies HCV, there are still no data on HBV and HCV among pregnant women in that region, hence fostering the need to study the prevalence and risk factors of HBV and HCV among pregnant women attending the antenatal care unit of the Bertoua Regional Hospital (BRH).

Still in Cameroon, A cross-sectional study at the Yaounde Central Hospital from January 1 to June 30, 2016, included 360 pregnant women who were screened for hepatitis B virus surface antigen (HbsAg) and VHCAb by rapid diagnostic test (DiaSpot Diagnostics, USA) followed by

confirmation of positive results by a reference laboratory, the results showed out that The prevalence of HbsAg and VHCAb were 9.4% (n = 34) and 1.7% (n = 6), respectively.

3. MATERIALS & METHODS

Inclusion criteria were Pregnant women aged of 19 years and above (58) who freely consented, and came for antenatal care visit at the maternity unit of the BRH, and had not been vaccinated against HBV within the study period; as well, the study excluded pregnant women less than 19 years and non-pregnant women. Those of them who had receive HBV vaccine at the period of the study were also excluded. The prospective health facility-based study setting was chosen because of the required study population of pregnant women who register for regular antenatal care visits. Moreover, data collected at a specific point in time was deemed adequate to establish a diagnosis of HBV virus, hence, justifying the choice of a cross-sectional study design, this is because testing for Hepatitis B and C virus has been made a routine test for all the pregnant women on their antenatal care visit at the Bertoua Regional Hospital and actually were free of charge during the study. A total of 400 pregnant women were consecutively sampled (non-probabilistic) registered for their visit during the study period and all were approached with a request and signed the informed consent to take part in the study, all of them gave their consent to participate in the study and they were consecutively enrolled to the study.

Participants were assigned codes for anonymity purposes, we used for HBV screening Diaspot HBsAg, these are step Hepatitis B Surface Antigen (HBsAg) test strip package insert and for HCV, Diaspot HCV virus anti-body (HCV-Ab) test strips. Those are immune-chromatographic strips for qualitative detection of antibodies and

antigens. Their sensitivity and specificity are above 99% and 98% respectively. Results were disclosed to participants with proper counselling; all infected pregnant women were counselled on the disease and referred for proper specialization care while the non-infected were counselled for HBV vaccination. Data were obtained using a well-structured questionnaire which was designed for the research and for laboratory analysis; questions elicited data to cover the objectives of the study, the questionnaire included seven sections, each focusing on a particular aspect to answer the research questions and gaps as well. The quantitative part of the questionnaire featured MCQ and Likert-scale questions allowing participant to rate their experiences, knowledge, feelings and attitudes. The questionnaires also included open-ended questions inviting participants to give other factors not mentioned. Frequencies (sums and percentages) were calculated for the socio-demographic factors and the different attitudes, feelings and practices towards HBV and HCV.

Tables displaying the frequency distribution for knowledge, attitude and practice towards HBV and HCV were entered into graph, each of the tables had frequencies for knowledge, maternal HBV/HCV preventive modes and practices, modes of transmission. Data were analyzed using Excel 2016 frequencies and percentages were determined.

4. RESULTS & DISCUSSION

[See Annex — Table 1: Socio-demographic information of pregnant women attending ANC at the Bertoua Regional Hospital]

The results showed that the majority of pregnant women (62%) were aged within the framed age (19-28), most of them (59.5%) were single,

32.5% of the pregnant women had no formal education, while 38.75% of them were housewives, 89.5% were Christian and more than half (76.25%) were multigravida.

Among the 400 pregnant women, 29 of them had hepatitis B, C and coinfection (HBV&HCV) for a general prevalence rate of (7.25%) that is HBV (4%), HCV (2.25%), and coinfection (1%). The (7%) Seroprevalence rate for Cameroonian HBV, HCV, and coinfection in pregnant women was reported in the study "Rates of HBV, HCV, HDV and HIV type 1 among pregnant women in Yaoundé, Cameroon" by (*Torimiro et al; 2024*) Their study found that (7.8%) of the 409 pregnant women were HIV-1 positive, with HIV/HBV coinfection observed in (12.5%) and HIV/HCV coinfection in (9.3%) of the HIV-positive women. Additionally, two women were co-infected with all three viruses (HIV/HBV/HCV).

5. CONCLUSION

In conclusion, viral Hepatitis B and C among pregnant women is a real public health problem, women have to be sensitized and counselled. Viral Hepatitis screening routine has to be systematic as stated by the World Health Organization and the Ministry of Public health in application; unawareness is the main cause of high prevalence rate. As well, healthcare workers have to be conscious while operating on a daily basis, they must observe hygiene rules, in order to reduce the risk of infections as large, thereby avoiding sharing healthcare materials among patients for the same purpose.
